

Custom AI solutions and governance

Generic assistants may not understand your business context or safely execute the work you need. Design a focused assistant or agent around approved knowledge, bounded tools, and measurable task quality, with governance built into the delivery approach.

Capabilities

- Assess task feasibility, business ownership, source quality, and permitted data use.
- Design permission-aware knowledge retrieval, source references, and handling of uncertain answers.
- Connect approved tools and Model Context Protocol servers with scoped permissions and action approvals.
- Test representative tasks, denied access, misleading inputs, and safe failure behavior.
- Define release decisions, human escalation, monitoring, change review, and retirement.

Deliverables

- A solution blueprint defining task boundaries, knowledge sources, permissions, and decision ownership.
- A scoped prototype demonstrating the agreed workflow and integration boundaries.
- An evaluation dataset and results report covering task quality, groundedness, and failure cases.
- A production-readiness backlog with release gates, monitoring requirements, and support ownership.

Business value

Establish whether a custom agent solves a real problem well enough to justify further investment. Measure task success, unsupported answers, safe failure, latency, and cost per useful interaction rather than relying on a polished prototype.

Start with a scoped use case and clear boundaries.

Bring representative tasks, approved information, an accountable owner, and intended integrations. Start with a bounded prototype; production deployment and expanded permissions require separate readiness and authorization decisions.
